

Assessing Water Content in solid transformer insulation from dynamic measurement of moisture in oil

Brian Sparling, SMIEEE
GE Energy, Canada

*IEEE PES Seminar
Vancouver BC
April 3rd 2008*

Moisture in insulation

In transformer, there is several sources of moisture:

Residual moisture from manufacturing process: Good drying process should result in less than 0.5% moisture in paper

Leaks: Gasket and/or joints could leak

Insufficient maintenance: To be effective, Silica gel system needs constant maintenance, any lapse could result in large amount of moisture into the transformer

Moisture in insulation

In transformer, there is several sources of moisture:

Paper degradation: The thermal degradation of paper does generate water

This water will generate yet more paper degradation

Moisture is strongly absorbed by paper, once inside the transformer, it is difficult to remove.

Moisture in insulation

Moisture in oil

- Can lead to water condensation

Moisture in winding paper is critical

- Reduces dielectric strength
- Increased risk of bubbling at high load
- Accelerates the rate of insulation aging

Moisture in pressboard barrier is critical

- Reduces dielectric strength

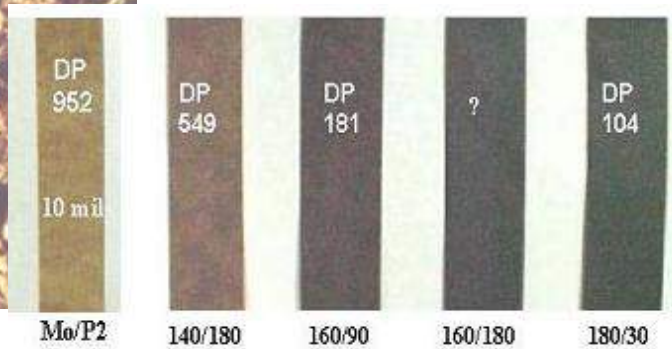

Only moisture in oil can be measured

Paper is found in many forms in winding insulation

Where does water come from?

Where does water go?

The water will also degrade the paper
HOH (water)

Impact of moisture in oil

V. Davydov, EPRI Moisture Management in Transformer Workshop, Nov.2002, Edison, New Jersey

Impact of moisture in oil

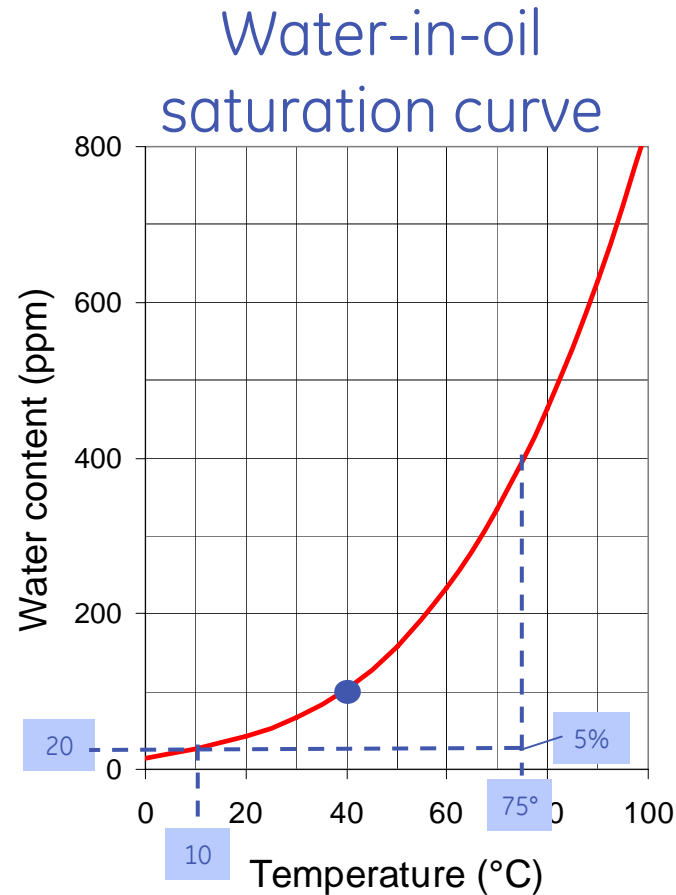

Sensors

Sensor Relative Humidity (RH%)

5%

Sensor Temperature(°C)

75°C

Output

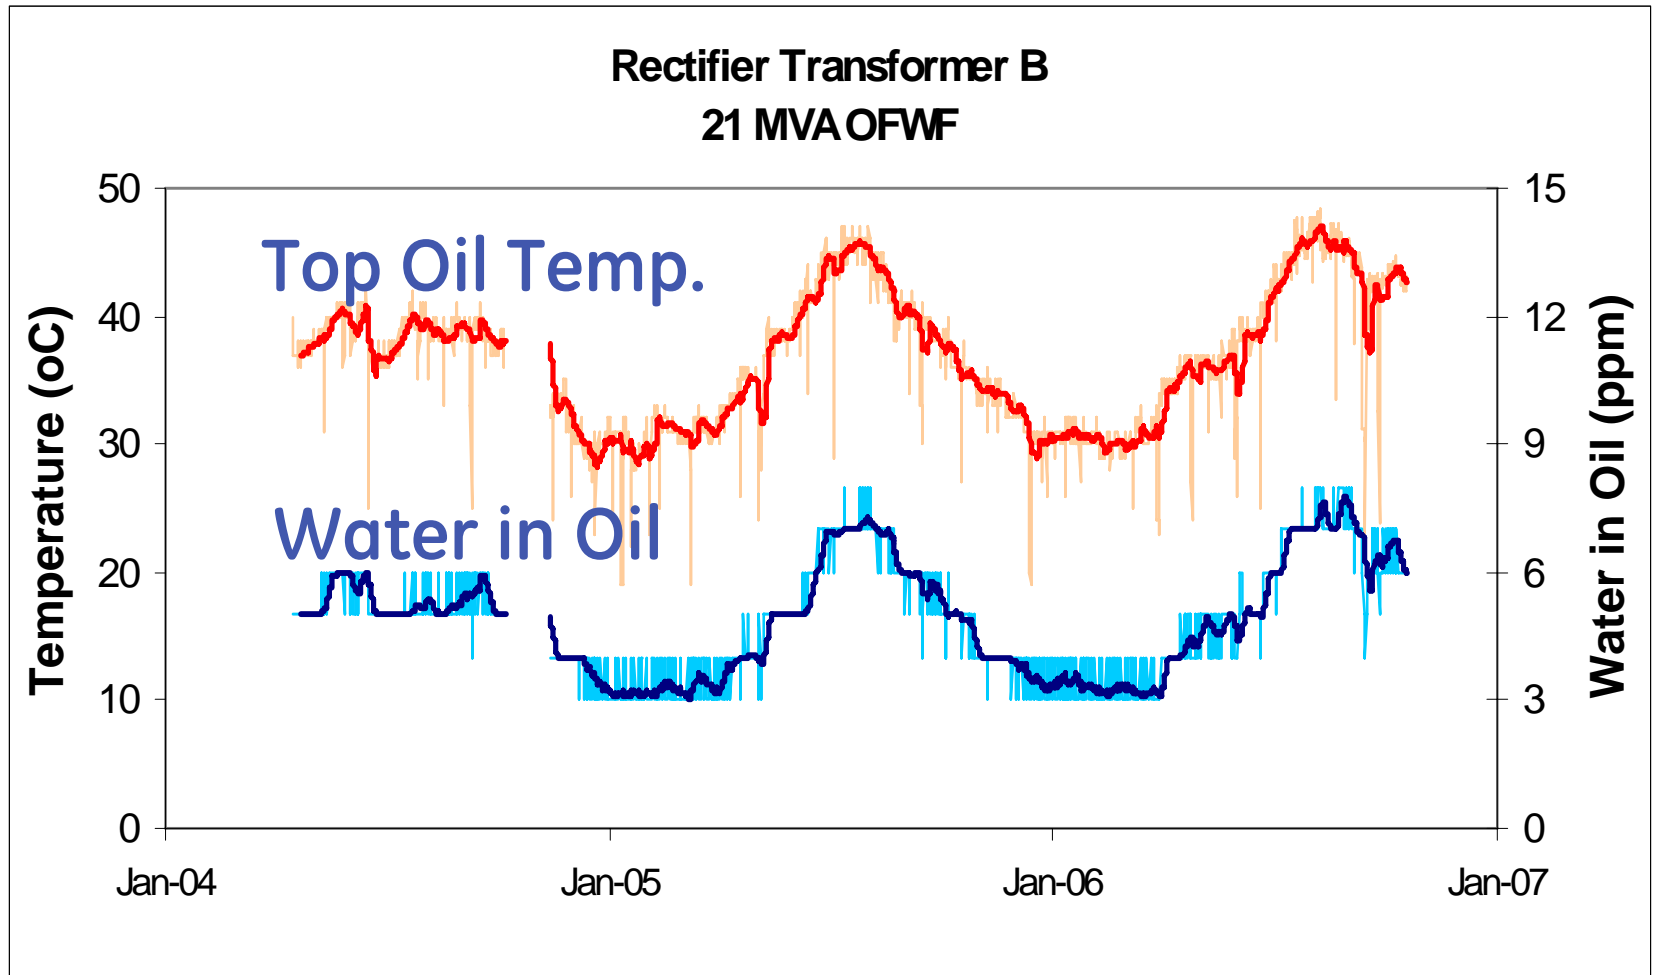

Absolute water content in oil (ppm)

20ppm

Condensation temperature (°C)

10°C

Change in water-in-oil concentration

Water content in oil varies with Temperature

Most of the water is stored in the solid insulation

Example of water distribution in a 25 MVA transformer with 3% moisture in paper

	40°C		80°C	
Oil (25 000litre)	10 ppm	0.25 kg	80 ppm	2.0kg
Paper (2500 kg)	3 %	75 kg	2.93%	73.25 kg
Total		75.25 kg		75.25 kg

- Most of the water is in the solid insulation
- Change in water content of oil does not entail a similar change in the water content of paper

Paper Aging

- *Definition, End of life criteria*
- *Contributing factors*

Insulation aging is irreversible

Moisture content in transformer insulation is a persistent concern

Aging transformers tend to build-up moisture

IEEE Std 62 – 1995:

- Dry 0-2%
- Wet 2-4%
- Very Wet 4.5% +

Only moisture in oil can actually be measured

Impact of moisture in paper

The amount of moisture in paper is a very important parameter to know, as it directly affects the following:

- Aging rate of the winding insulation
- Bubbling temperature (limits the amount of overloading of a transformer)
- Dielectric strength of the barriers at the bottom of the winding

Water accelerates ageing of Kraft paper

Cigre publication 323 Oct. 2007

Oxygen accelerates ageing of paper

- Presence of oxygen has, in laboratory experiments shown an ageing acceleration by a factor 2-3
- Above 2000 ppm O_2 showed concentration independent ageing rates
- Oxygen saturated 30 000 ppm O_2
- Oxygen free 300 ppm O_2

Cigre Brochure 323, October 2007

Example of Winding Paper Degradation

Evolution of fault at weak points

The weak points are candidates for a possible failure

V. Sokolov Cigre Colloquium 1997

Impact of moisture in winding insulation

- Increased risk of releasing bubbles at high load

Residual
water

T.V.

Example of Overheating

V. Davydov EPRI Moisture Seminar 2002

Moisture reduces dielectric strength of pressboard barriers

Moisture can promote tracking discharges on pressboard barriers

Surface discharges are more likely on angle rings

Wet Barriers = Strong Discharges

Alstom T&D, Merida, 2003

Assessing Water Content in Transformer Solid insulation

Determination of water in solid insulation from water in oil

The problem:

- Should we use absolute water content in oil (ppm) or Relative Saturation (RS)?
- Is water content uniform through the transformer solid insulation?
- How do we handle the diffusion time between paper and oil?

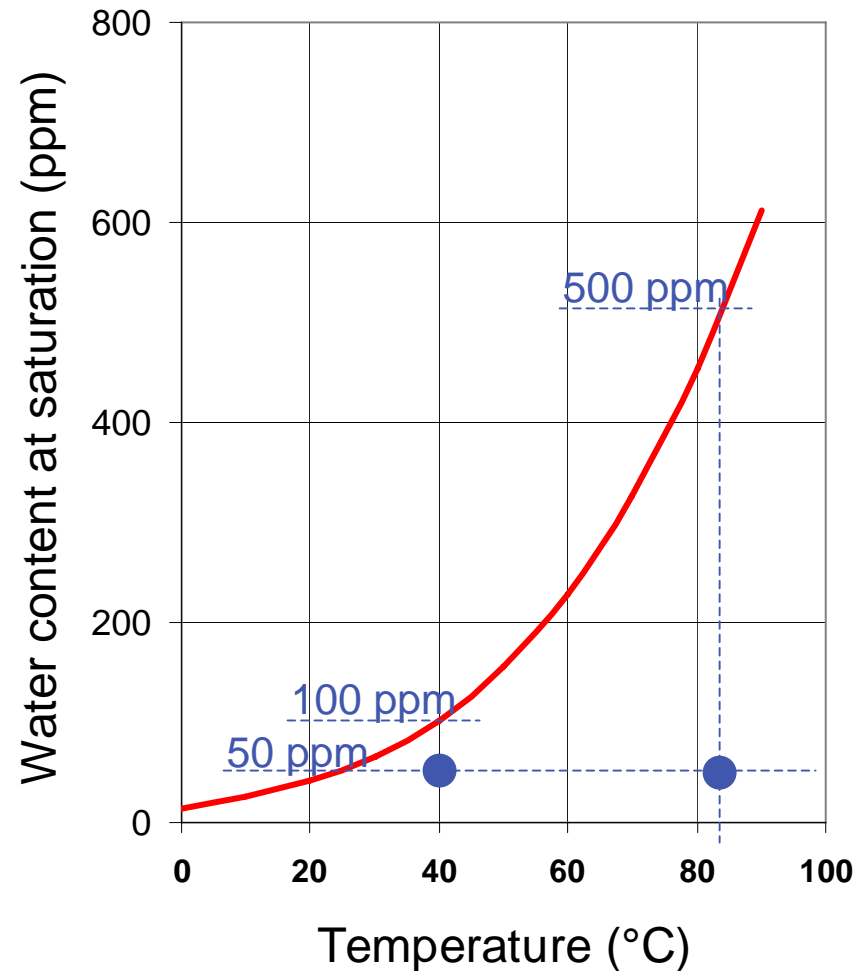

Oil saturation characteristics

- Water content in oil can be expressed in ppm
- This value must be related to oil saturation characteristics
- But saturation characteristic vary with type of oil and oil condition
- Therefore it is more convenient to consider Relative Saturation (RS)

Relative Saturation (RS)

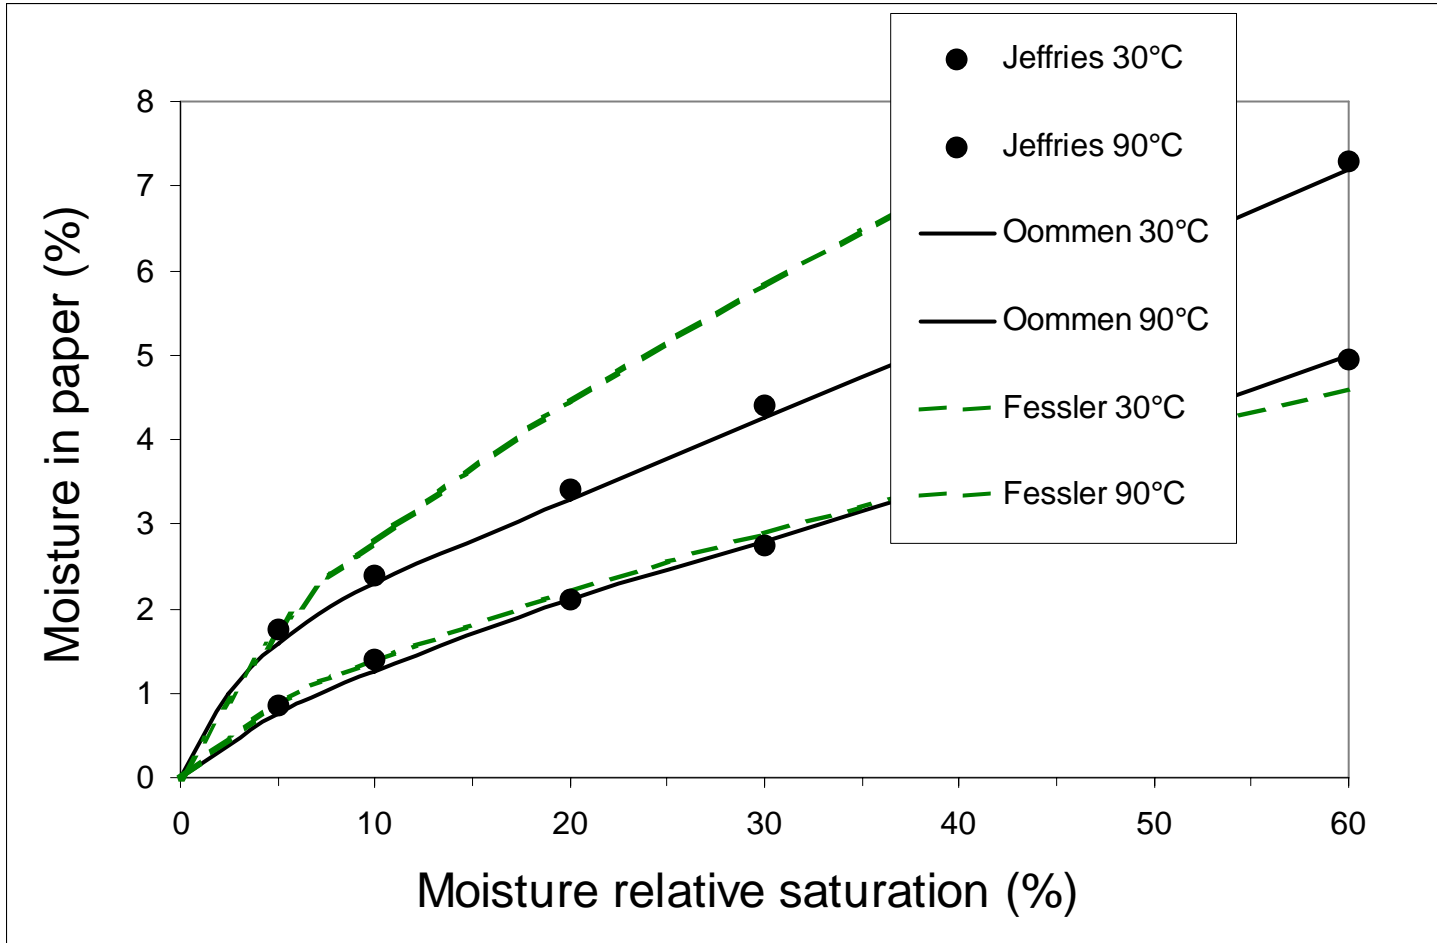

- Relative saturation is the moisture content relative to the saturation value at a given temperature
- At equilibrium, RS in oil = RS in paper
- It varies within the transformer
- Example:
 - Sensor: 40°C, RS = 50%
 - Hot spot: 85°C, RS = 10%

Moisture Migration Summary

- Equilibrium curves exist to relate moisture in paper to relative saturation in oil.
- These curves assume Equilibrium exists (the moisture has stopped moving between the oil and paper)
- But this is never the case.
- Many people make errors in using these charts, 'blindly' without considering equilibrium conditions which must exist, and their mistakes can be costly

Assessing Water Content in Transformer Solid insulation

Moisture in paper

Equilibrium curves are now available to convert moisture in oil into moisture in paper without considering oil saturation characteristics

But we still need:

- Temperature of oil-paper interface
- Diffusion time constant
- Facility for integrating results over long period of time

Moisture Migration Summary

- Paper at different temperatures inside the transformer will will have different moisture levels
- Different areas of the insulation system have different thickness (winding insulation versus barrier insulation)
- The Equilibrium condition therefore will take much longer for barrier insulation versus winding insulation

Typical diffusion time constant (in days)

Insulation Thickness

Temperature	1mm	2mm	4mm
80 °C	0.9	3.6	14
60 °C	4.2	17	67
40 °C	20	79	317
20 °C	93	373	1493

Moisture in paper varies within the transformer

Guided convection flow through disk windings

Area of Interest for moisture in paper

Migration of moisture in transformers

- Moisture content in solid insulation, is not a single value
- It appears impractical to assess the moisture content of the thick insulation
- Lowest part of pressboard barriers is the most critical location and should determine needs for drying
- Sensitivity analysis indicates that the value assigned to diffusion time constant is not critical

Migration of moisture in transformers

- There is a correlation between the amount of water in the oil and in the paper
- However, this correlation is dynamic and is changing as a function of transformer loading
- The dynamics of the distribution of water in the transformer is quite complex and changing

Moisture inside the transformer moves back and forth between the oil and paper by diffusion as a function of temperature

What to do?

Hydran M2

Advanced Gas and Moisture monitor

- H₂ and CO
- Moisture in oil
- Trending
- 4 analog inputs
- Data Logging
- Networking
- Integrated Modem/TCP-IP

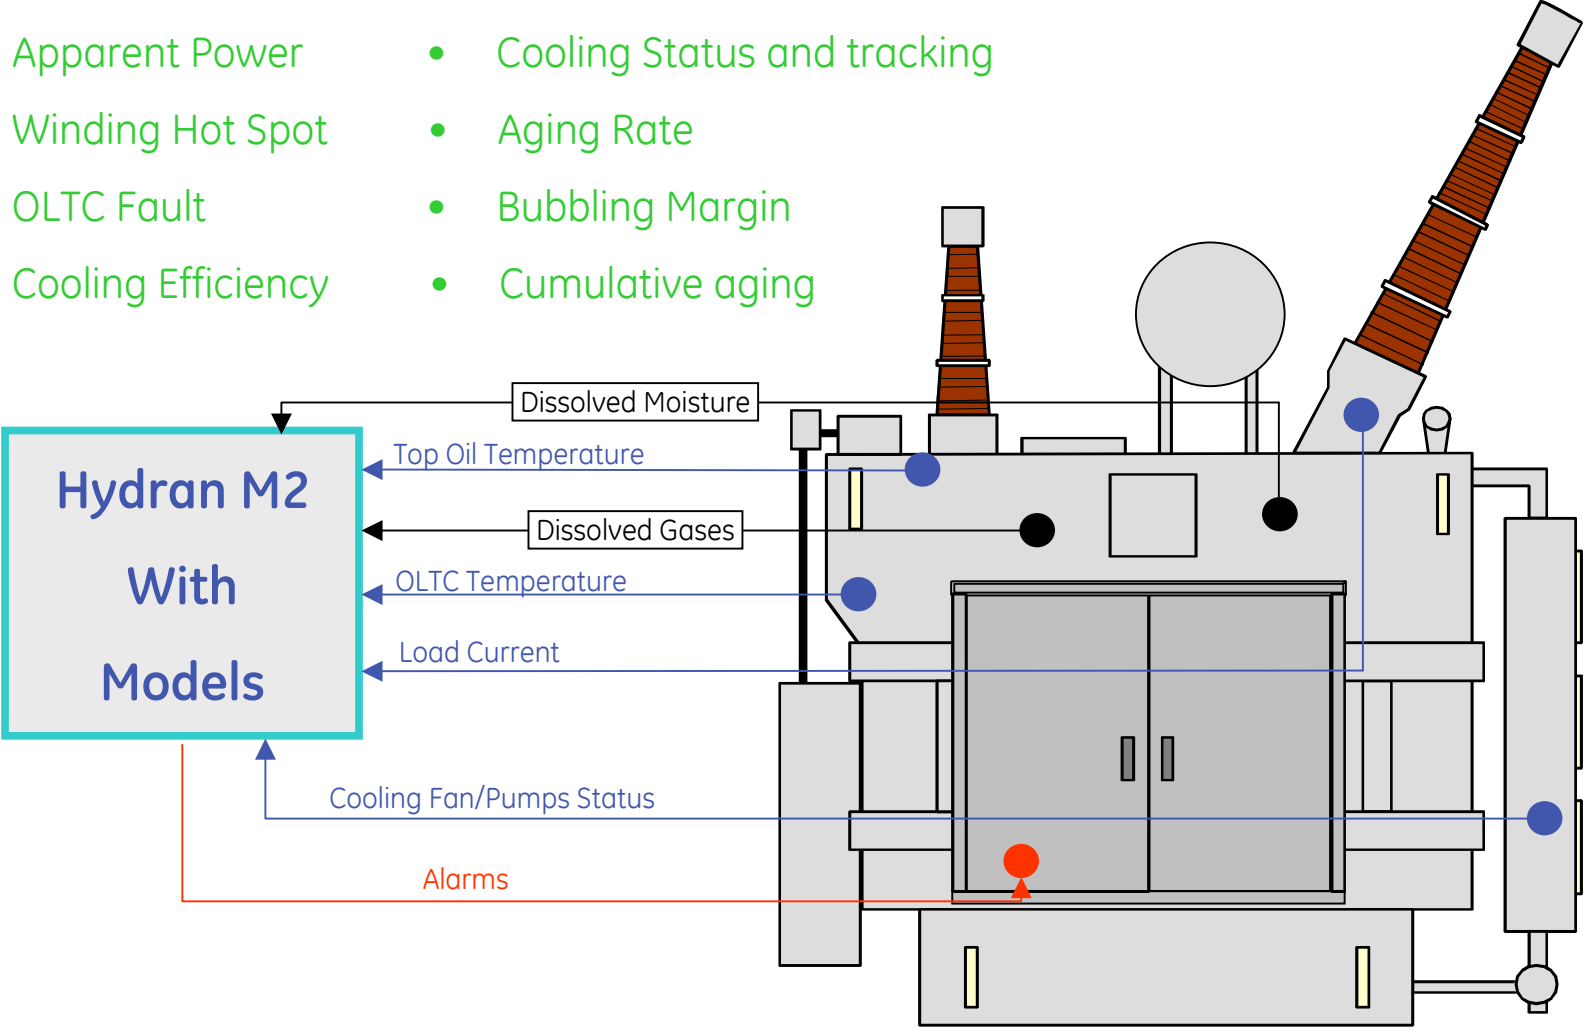

Typical HYDRAN M2 Installation

The Hydran M2 as Advanced Transformer Monitor

- Incipient Fault
- Apparent Power
- Winding Hot Spot
- OLTC Fault
- Cooling Efficiency
- Moisture in Oil, in Windings and in Barriers
- Cooling Status and tracking
- Aging Rate
- Bubbling Margin
- Cumulative aging

How degraded is my insulation?

Detection of paper degradation

CO₂ / CO

- **CO₂/CO ratios < 3** indicate fault involving paper degradation
- **CO₂** can also come from atmosphere in open breathing transformers
- **CO** can come from oil oxidation, paint, varnishes and phenolic resins

Detection of paper degradation from furanic compounds

Several furanic compounds are generated during paper decomposition

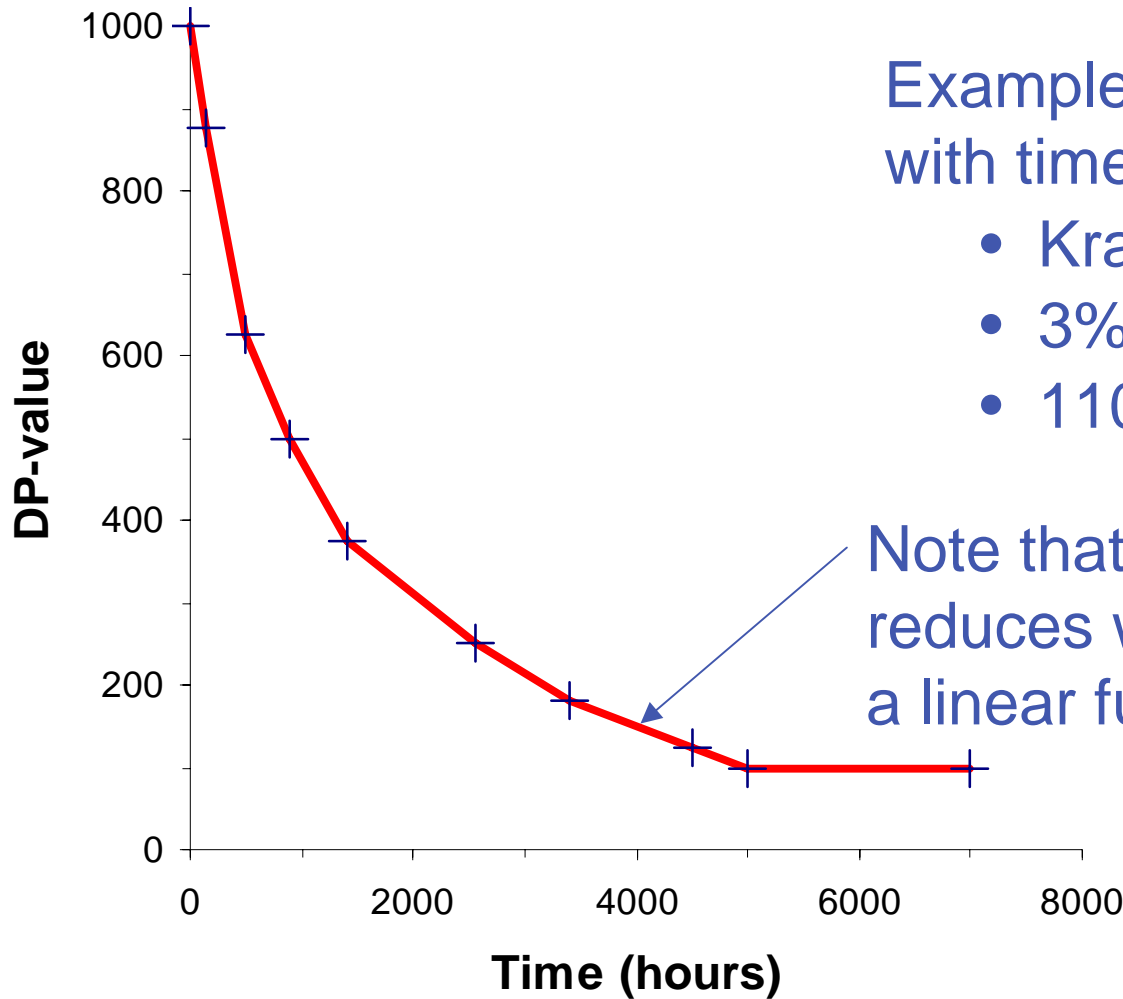

2FAL is the most stable and most abundant compound

Detection of paper degradation from furanic compounds

Increasing furanic compound content correlate with falling DP

Reduction of DP with time

Example of DP reduction with time for

- Kraft paper
- 3% water content
- 110°C

Note that rate of DP reduction reduces with time; aging is not a linear function

Mechanical strength is reduces with DP

- Mechanical strength is a function of length of cellulose chains in fibres
- Degree of polymerisation (DP) in cellulose fibres describes ageing condition

▪ DP of 200 correspond to remaining strength of about 30%

Cigre Publication 323, Oct. 2007

CORRELATION BETWEEN 2-FAL and DPV

0% 25% 50% 75% 100% Residual Life

2-FURALDEHYDE (ppb, microg/L)

DEGREE OF POLYMERISATION

In Conclusion

- As temperature and load change, so does the movement of water inside the transformer, between the paper and the oil
- In Practice, the perfect equilibrium needed to use the published curves almost never exist in a transformer
- Only a dynamic model, computed online in real time, can make a good evaluation of the amount of moisture in the paper, in the areas of interest
